

What I learned from the sources:

For a bit of clarity, I don't know much about web coding or the front end portion of full stack development. The first thing I learned was what exactly those positions are, and their value. The most valuable piece of information was how HTML relates to CSS and JavaScript. HTML is only formatting, CSS is only styling and JavaScript (and other languages) are used for functionality. I skipped over the framework portions because we aren't using them through this class. While they didn't dive too deeply into it in the video, I know from past experience how important github is to all computer science development. I would've liked to learn more about how web design has changed over the last few decades but I understand that wouldn't be as helpful as other information (learning tools, frameworks, etc). Content management services (CMS) generate api's from a custom Ui which can be used elsewhere. Server-side work is interesting to me, learning about the various languages used is valuable. Serverless architecture is a cheap way to run serverside code without having a server; it is cheap because you only pay for the time the code is running and not overtime. Web assembly allows you to run highly efficient code very quickly, it can use languages that I have learned. While web assembly isn't as good looking or readable as javascript, in terms of sheer computational efficiency it can't be beat.
